The Benefits of Commodity Investment

Introduction

Historically, direct commodity investments have been a minor part of investors' asset allocation decision. In contrast, indirect investment (e.g., equity or debt ownership of firms specializing in direct commodity market production) was the principal means of obtaining claims on commodity investment. In recent years, however, investable commodity indices and commodity-linked assets have increased the number of available direct commodity-based investment products. In addition, there is evidence (Schneeweis et al., 1997b that indirect commodity investment, through debt and equity instruments in commodity-linked firms, does not provide direct exposure to commodity price changes). However, there is little information on the expected, as well as the actual risk and return performance, of a wide variety of investable commodity indices or commodity linked products that have been marketed. The purpose of this study is, first, to detail the various theoretical arguments for the risk and return advantages for real commodity investment and, second, to test if currently available investable commodity forms such as the Goldman Sachs Commodity Index (GSCI), Standard & Poor's Commodity Index (S&PCI), or Dow Jones-AIG Commodity Index (DJ-AIG CI) offer means to obtain the prescribed theoretical risk and return processes embedded in commodity investment.

In the following section, the basis for and the structure of alternative indirect (e.g., stock funds) as well as direct passive and active option- and futures-based investable commodity products are reviewed. The expected return and risk structure for various direct 'long-only' futures-based investable commodity indices are analyzed as part of a fully diversified portfolio (stocks, bonds, hedge funds, and real estate). Results indicate that the indices have sources of risk and return (e.g. roll return, real options) that are distinct from traditional assets such as stocks and bonds as well as managed futures or hedge fund benchmark indices and offer investors an important area of diversification (Schneeweis et al., 1997a). Conclusions and suggestions for future studies are discussed in the final section.

Commodity Investment in Asset Management

The increased use of commodity trading vehicles in investment management has led practitioners to create investable commodity indices and products that offer unique performance opportunities for investors in physical commodities. As is true for stock and bond performance, as well as investment in managed futures and hedge fund products, commodity-based products have a variety of uses. Besides being a source of information on cash commodity and futures commodity market trends, they are used as performance benchmarks for evaluation of commodity trading advisors and provide a historical track record useful in developing asset allocation strategies. However, the investor benefits of commodity or commodity-based products lie primarily in their ability to offer risk and return trade-offs that cannot be easily replicated through other investment alternatives. Previous research (Schneeweis et al., 1997b) indicates that direct stock and bond investment offers little evidence of providing returns consistent with direct commodity investment. To the degree that firms hedge a major portion of the commodity risk (Chung, 2000), even commodity-based firms may not be exposed to the risk of commodity price

movement. Thus for investors, direct commodity investment may be the principal means by which one can obtain exposure to commodity price movements.

Academic research has examined the economic determinant of returns to commodity investment. For example, Fama and French (1988) and Schneeweis, Spurgin, and Georgiev (2000) identified a strong business cycle component in the variation of spot and futures prices of industrial metals. Fama and French (1987; 1988) perform tests of the theory of storage and present empirical evidence that in periods of increasing volatility and risk, convenience yields increase for a wide variety of metals prices (e.g., aluminum, copper, nickel and lead). The theory of storage (Kaldor, 1939; Working, 1948; 1949; Telser, 1958) splits the difference between the futures price and the spot price into the forgone interest from purchasing and storing the commodity, storage costs and the convenience yield on the inventory. Convenience yield reflects an embedded consumption timing option in holding a storable commodity. Further, the theory predicts an inverse relationship between the level of inventories and convenience yield – at low inventory levels convenience yields are high and vice versa. A related implication is that the term structure of forward price volatility generally declines with time to expiration of the futures contract – the so-called "Samuelson (1965) effect." This is caused by the expectation that, while at shorter horizons mismatched supply and demand forces for the underlying commodity increase the volatility of cash prices, these forces will fall into equilibrium at longer horizons.

Litzenberger and Rabinowitz (1995) observe that oil futures prices are often below spot prices--futures markets are backwarddated. Strong backwardation occurs when futures prices are below current spot prices. In weak backwardation, discounted futures prices are below spot prices. Litzenberger and Rabinowitz explain the phenomenon with the existence of "real options" under uncertainty. They show that production occurs only if discounted futures are below spot prices and strong backwardation emerges if the riskiness of future prices is sufficiently high. A major consequence of a declining term structure of forward prices for investment in commodity futures is the opportunity to capture a positive roll return as investment in expiring contracts is moved to cheaper new outstanding contracts.

The diversification benefits of commodities have been studied in Ankrim and Hensel (1993, Anson (1998), Becker and Finnerty (2000), and Schneeweis and Spurgin (1997b), among others. For instance, Becker and Finnerty find that the inclusion of portfolios of long commodity futures contracts (CRB and GSCI) improves the risk and return performance of stock and bond portfolios for the period of 1970 through 1990. They observe that the improvement is more pronounced for the 1970s than the 1980s due to the high inflation of the 1970s with commodities acting as an inflation hedge. Futures prices were also found to have little value in predicting inflation.

The principal argument for investing in commodities is that investing in assets that rise in price with inflation provides a natural hedge against losses in equity and debt holdings that typically lose value during periods of unexpected inflation (see Bodie, 1983; Greer, 1978; Halpern and Warsager, 1998; Becker and Finnerty, 2000). While previous studies have concentrated on measuring commodity returns during high and low inflation periods, the real benefits of commodity investment may lie in periods of unexpected rises in inflation. Anticipated inflation, which results in high bond yields and high equity earnings growth, may result in positive real

returns for stocks and bonds. It is the unexpected inflation that should cause concern to every serious investor. The importance of being exposed directly to commodity price movements is due to the possibility of obtaining natural sources of commodity return and inflation protection. In periods of unexpected inflation, market conditions may often lead to increasing commodity prices and weakness in stocks and bonds.

Commodity Indices

One of the most attractive aspects of commodity investment today is that there are now a number of passive indices that are fully investable. In addition to providing a simple method to access these returns, commodity indices have a number of other uses. Commodity indices are a source of information on cash commodity and futures commodity market trends, are used as performance benchmarks for evaluation of commodity trading advisors, and provide a historical track record useful in developing asset allocation strategies.

Commodity indices are generally based on the returns of futures contracts and/or cash markets. Included in this group are the Dow Jones-AIG, Standard and Poor's, and Goldman Sachs. These indices provide returns comparable to passive long positions in listed futures contracts. Commodity indices attempt to replicate the return available to holding long positions and short in agricultural, metal, energy, or livestock investment. Since the cost-of-carry model insures that the return on a fully margined position in a futures contract should mimic the return on an underlying spot deliverable, futures contract returns are often used as a surrogate for cash market performance. Futures-contract-based commodity indices have three separate sources of return: price, roll, and collateral return. Price return derives from changes in commodity futures prices. Roll return arises from rolling long futures positions forward through time. It may capture a liquidity premium through an increased convenience yield in periods of high volatility of the underlying due to demand and supply shocks. Collateral return assumes the full value of the underlying futures contracts are invested at a risk-free interest rate. This is equivalent to assuming an investor posts 100% margin with Treasury bills.

Data, Methodology, and Empirical Results

The four primary commodity indices used in this analysis are as follows:

GSCI: The Goldman Sachs Commodity Index (GSCI) is a world production-weighted commodity index that has become one of the premier global commodity benchmarks for measuring investment performance in the commodity markets. It is composed of 24 liquid exchange-traded futures contracts: six energy products, five industrial metals, eight agricultural products, three livestock products and two precious metals. The quantity of each commodity in the index is determined by the average quantity of production in the last five years of available data.

Subindices are calculated for agricultural, energy, industrial, livestock, and precious metals contracts. Three GSCI indices are published: excess return, total return and spot. The excess

return index measures the returns accrued from investing in uncollateralized nearby commodity futures, the total return index measures the returns accrued from investing in fully-collateralized nearby commodity futures, and the spot index measures the level of nearby commodity prices. The GSCI was officially launched in 1992.

Dow Jones AIG: The Dow Jones-AIG Commodity Index (DJ-AIG CI) is an arithmetically calculated price index composed of futures contracts on 20 physical commodities. The major commodity sectors present in the index are: Energy (including petroleum and natural gas), Petroleum (including crude oil, heating oil and unleaded gasoline), Precious Metals, Industrial Metals, Grains, Livestock and Softs. With the exception of aluminum, nickel and zinc (industrial metals) which trade on the London Metal Exchange (LME), all other commodities that form DJ-AIG commodity index are traded on U.S. exchanges.

To determine the relative quantities of included commodities, the DJ-AIGCI relies primarily on liquidity data, along with dollar-adjusted production data. It considers the relative amount of trading activity associated with a particular commodity to determine its weight in the index. In addition, to insure diversified commodity exposure, the DJ-AIGCI relies on several diversification rules. Among these rules are the following:

- No related group of commodities (e.g., energy, precious metals, livestock and grains) may constitute more than 33% of the index.
- No single commodity may constitute less than 2% of the index.

The DJ-AIGCI is re-weighted and re-balanced every January. Re-balancing and re-weighting is designed to reduce the exposure of the index to commodities that have appreciated in value and to increase the index's exposure to commodities that have underperformed. During the course of the year, commodity weights are free to increase or decrease as their values increase or decrease, subject to the two limits imposed above. Therefore, this index is a momentum-type index. The DJ-AIGCI was launched in 1991.

S&P Commodity Index: S&P Commodity Index (S&PCI) a geometrically calculated price index comprising futures contracts on 17 consumable commodities within 6 sectors. Gold is excluded. S&PCI index portfolio is effectively rebalanced real-time, maintaining constant dollar exposure across underlying commodities. Index weights for each commodity are determined using the dollar value of commercial open interest in futures markets. Commodity weights are adjusted to reflect double-counting. Upstream commodities (e.g., crude oil) are adjusted downward to account for their presence in related downstream commodities (e.g., heating oil and unleaded gas).

Jefferies Commodity Performance Index: Jefferies Commodity Performance Index (JCPI) is designed to be a straightforward, highly liquid and broadly diversified index that demonstrates long-term historical returns and correlative properties. The Index was designed explicitly to address the needs of institutional investors seeking diversified commodity exposure. The Index was created at Jefferies Financial Products, LLC by a team of seasoned professionals with extensive experience in the field of commodities as an asset class. Jefferies Commodity Performance Index - High Energy possesses many features of the Jefferies Commodity Performance Index.

Methodology and Data

Monthly returns are derived for a series of stock, bond, commodity, and hedge fund indices for the time period from January 1990 through December 2004 (Exhibit 5 until December 2003). Data was obtained for each of the indices and relevant subindices (GSCI, S&PCI, DJ-AIG CI, JCPI), as well as the Standard and Poor's 500 and MSCI World Stock Indices, the Lehman Brothers U.S. Government/Corporate and World Bond Indices, the Hedge Funds Composite Index[1], three-month Treasury bill yields, and the U.S. Consumer Price Index. Stock, bond, commodity, currency and inflation indices are obtained from DataStream and Ibbotson Associates.

Empirical Results

In Exhibits 1 and 2, the average monthly returns and standard deviations of monthly returns, Sharpe ratios, minimum monthly returns, and correlations to the GSCI Index, S&PCI Index, and DJ-AIG CI Index for the sample of stock, bond, hedge fund and commodity indices over the January 1990 through December 2004 period are presented, both as stand-alone investments as well as in various portfolio groupings.

Exhibit 1

Commodity Index Performance 1990-2004

	GSCI	S&PCI	DJ-AIG CI	JCPI	HF Composite	S&P 500	Lehman Gov/Corp	MSCI World	Lehman Bond Global
Annualized Returns	7.08%	4.78%	6.89%	14.41%	13.46%	10.94%	7.77%	7.08%	8.08%
Annualized Standard Deviation	19.26%	12.85%	11.85%	15.46%	5.71%	14.65%	4.46%	14.62%	5.23%
Sharpe Ratio	0.15	0.04	0.22	0.65	1.61	0.45	0.78	0.19	0.72
Minimum Monthly Return	-14.41%	-8.97%	-7.54%	-9.72%	-6.92%	-14.46%	-4.19%	-13.32%	-3.66%
Correlation GSCI	1.00	0.84	0.89	0.95	0.09	(0.08)	0.03	(0.06)	0.06
Correlation S&PCI	0.84	1.00	0.91	0.88	0.13	0.03	0.02	0.05	0.07
Correlation DJ AIG CI	0.89	0.91	1.00	0.94	0.19	0.08	0.03	0.15	0.12
Correlation JCPI	0.95	0.88	0.94	1.00	0.21	0.09	0.05	0.14	0.14

The annualized return, standard deviation, and Sharpe ratio for the GSCI composite index are 7.08 percent, 19.19 percent, and 0.15, respectively (see Exhibit 1). Results for the S&PCI composite index and DJ-AIG CI composite index differ to some extent. Except the JCPI, both in absolute terms and on a risk-adjusted basis, commodities have underperformed US and world bonds and equities. Nonetheless, commodities may produce investment benefits when considered as an addition to a diversified portfolio.

The decision to add an investment product to an existing portfolio depends on the relative means and variances of the investment vehicle and the existing portfolio as well as the correlation between the investment vehicle and the portfolio. The low or negative correlations of GSCI returns with returns to the S&P 500 (-0.08), Lehman Gov./Corp. Bond (0.03), and the HF Composite Index (0.10) suggest such potential benefits. Similarly, when considered as a global investment, the GSCI exhibits low or negative correlations with the MSCI World Index (-0.06)

[1] The Hedge Funds Composite Index is created as follows: between 1990 and 1993 it is an equally weighted portfolio of EACM 100 and HFR, since 1994 it is an equally weighted portfolio of EACM 100, HFR, and CSFB.

and the Lehman Global Bond Index (0.06). Comparable results hold for the S&PCI, DJ-AIG CI, and JCPI (see Exhibit 1).

The above relationships are reflected in the performance of investment portfolios including the GSCI, S&PCI, DJ-AIG CI or JCPI (see Exhibit 2). When added to a domestic portfolio of stocks and bonds, the GSCI helps reduce the standard deviation of the portfolio from 7.94 percent to 7.19 percent. Additionally, risk-adjusted performance (Sharpe ratio) improves; it is 0.67 for the domestic stock/bond portfolio, and goes up to 0.73 when the portfolio includes GSCI too. Similarly, when added to a global stock/bond portfolio, the GSCI reduces volatility from 8.29 percent to 7.55 percent and increases the Sharpe ratio from 0.43 to 0.50. Similar results hold for portfolios that include S&PCI, DJ-AIG CI, and JCPI.

Exhibit 2

Performance of Portfolios Including Commodity Indexes (1990-2004)

Commodity Index: GSCI	**Portfolio I**	**Portfolio II**	**Portfolio III**	**Portfolio IV**	**Portfolio V**	**Portfolio VI**
	S&P 500 & Lehman Bond	S&P 500, Lehman Bond, & GSCI	S&P 500, Lehman Bond, GSCI & HF Comp.	MSCI World & Lehman Global	MSCI World, Lehman Global & GSCI	MSCI World, Lehman Global, GSCI & HF Comp.
Annualized Returns	9.64%	9.51%	9.99%	7.86%	8.07%	8.56%
Annualized Standard Deviation	7.94%	7.19%	6.87%	8.29%	7.55%	7.16%
Sharpe Ratio	0.67	0.73	0.83	0.43	0.50	0.60
Minimum Monthly Return	-6.25%	-6.18%	-6.28%	-5.61%	-5.67%	-5.77%
Correlation GSCI	(0.07)	0.47	0.22	(0.03)	0.48	0.24

Commodity Index: S&PCI	**Portfolio I**	**Portfolio II**	**Portfolio III**	**Portfolio IV**	**Portfolio V**	**Portfolio VI**

Annualized Returns	9.64%	8.84%	9.64%	7.86%	7.42%	8.22%
Annualized Standard Deviation	7.94%	6.93%	6.88%	8.29%	7.26%	7.15%
Sharpe Ratio	0.67	0.66	0.78	0.43	0.43	0.55
Minimum Monthly Return	-6.25%	-6.28%	-6.33%	-5.61%	-5.76%	-5.82%
Correlation S&PCI	0.03	0.40	0.23	0.06	0.41	0.25

Commodity Index: DJ-AIG CI	**Portfolio I**	**Portfolio II**	**Portfolio III**	**Portfolio IV**	**Portfolio V**	**Portfolio VI**
	S&P 500 & Lehman Bond	S&P 500, Lehman Bond, & DJ-AIG CI	S&P 500, Lehman Bond, DJ-AIG CI &HF Comp.	MSCI World & Lehman Global	MSCI World, Lehman Global & DJ-AIG CI	MSCI World, Lehman Global, DJ-AIG CI &HF Comp.
Annualized Returns	9.64%	9.65%	10.26%	7.86%	8.47%	9.09%
Annualized Standard Deviation	7.94%	6.76%	6.72%	8.29%	7.06%	6.89%
Sharpe Ratio	0.67	0.79	0.89	0.43	0.59	0.70
Minimum Monthly Return	-6.25%	-6.27%	-6.33%	-5.61%	-5.76%	-5.82%
Correlation DJ AIG CI	0.08	0.43	0.27	0.18	0.49	0.35

Commodity Index: JCPI	**Portfolio I**	**Portfolio II**	**Portfolio III**	**Portfolio IV**	**Portfolio V**	**Portfolio VI**
	S&P 500 & Lehman Bond	S&P 500, Lehman Bond, & JCPI	S&P 500, Lehman Bond, JCPI & HF Comp.	MSCI World & Lehman Global	MSCI World, Lehman Global & JCPI	MSCI World, Lehman Global, JCPI & HF Comp.
Annualized Returns	9.64%	10.51%	10.18%	7.86%	10.00%	9.68%
Annualized Standard Deviation	7.94%	7.20%	6.93%	8.29%	7.39%	7.02%
Sharpe Ratio	0.67	0.86	0.85	0.43	0.77	0.77
Minimum Monthly Return	-6.25%	-6.32%	-6.35%	-5.61%	-5.81%	-5.84%
Correlation JefCI	0.10	0.51	0.33	0.17	0.56	0.39

Note:
Portfolio I: 50% S&P 500 and 50% Lehman Gov./Corp. Bond
Portfolio II: 40% S&P 500, 40% Lehman Gov./Corp. Bond, and 20% Commodity Index
Portfolio III: 40% S&P 500, 40% Lehman Gov./Corp. Bond, 10% Commodity Index, and 10% HF Composite Index
Portfolio IV: 50% MSCI World and 50% Lehman Global Bond
Portfolio V: 40% MSCI World, 40% Lehman Global Bond, and 20% Commodity Index
Portfolio VI: 40% MSCI World, 40% Lehman Global Bond, 10% Commodity Index, and 10% HF Composite Index

The impact of including DJ-AIG Commodity Index in a stock/bond portfolio is more evident. At the domestic level, DJ-AIG CI helps reduce the standard deviation of the portfolio from 7.94 percent to 6.76 percent at the expense of increasing the Sharp ratio by about 0.12. At the global level, the standard deviation adjusts from 8.29 percent to 7.06 percent when DJ-AIG CI is added to the stock/bond portfolio.

In almost all cases, adding more assets, such as hedge funds, to the portfolio results in improved performance.

Exhibit 3 shows the performance statistics for the GSCI and DJ-AIG component subindices. Even though the performance is unimpressive on its own (barring the GSCI Energy and DJ-AIG subindices), the low or negative correlations with stock, bond, hedge fund, and real estate indices shown in Exhibit 4 again suggest that investors who wish to target particular commodity sectors may still benefit from the addition of that sector to a diversified portfolio of assets.

Exhibit 3

Performance of GSCI Subindexes (1990 - 2004)

	GSCI Agriculture	GSCI Energy	GSCI Industrial Metals	GSCI Livestock	GSCI Non-Energy	GSCI Precious Metals
Annualized Returns	-2.49%	9.77%	5.42%	3.58%	1.21%	1.66%
Annualized Standard Deviation	13.99%	32.48%	16.98%	13.75%	9.04%	12.68%
Sharpe Ratio	-48.51%	16.87%	6.66%	-5.14%	-34.08%	-20.69%
Minimum Monthly Return	-10.57%	-22.14%	-12.89%	-15.76%	-6.27%	-11.03%

Performance of DJ-AIG CI Subindexes (1990 - 2004)

	DJ-AIG Energy Index (TR)	DJ-AIG Petroleum Index (TR)	DJ-AIG Livestock Index (TR)	DJ-AIG Grains Index (TR)	DJ-AIG Ind Metals Index (TR)	DJ-AIG Prec Metals Index (TR)	DJ-AIG Softs Index (TR)
Annualized Return	12.55%	13.39%	2.20%	-1.49%	4.33%	2.17%	1.72%
Annualized StDev	29.32%	29.21%	14.07%	17.85%	17.23%	14.01%	17.70%
Sharpe Ratio	28.19%	31.14%	-14.82%	-32.37%	0.25%	-15.15%	-14.53%
Minimum Monthly Return	-21.75%	-22.50%	-12.57%	-14.36%	-11.59%	-13.85%	-12.00%

Commodities as an Inflation Hedge

A significant part of the benefit of direct commodity investment is said to derive from unique fluctuations in commodity values as a function of shifting economic forces. One such aspect of the return process of commodities is that commodity cash prices benefit from periods of unexpected inflation, whereas stocks and bonds suffer. As a result, commodities should provide a positive return while other asset classes decrease in value. This premise is tested by calculating the correlation of spot commodity index returns (as well as stock, bond, hedge fund, and real estate returns) with a proxy for unexpected inflation. The proxy used is the monthly change in the rate of inflation.

Exhibit 4

Factor Correlations (1990 - 2004)

	S&P 500	Lehman Bond	Change in Credit Spread (Baa-Aaa)	Change in VIX	Change in Term Spread	Change in Bond Vol	Change in Stk Vol	Unexpexcted Inflation

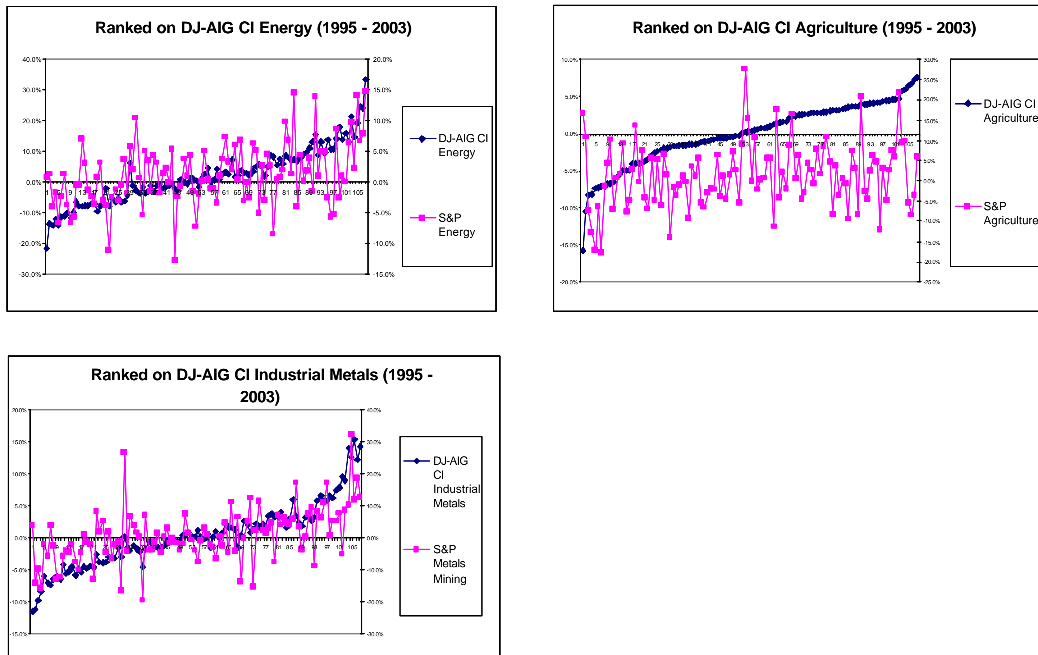
Note: Monthly changes in inflation beyond one standard deviation of the average are used to proxy for unexpected inflation

Direct and Indirect Commodity Investment

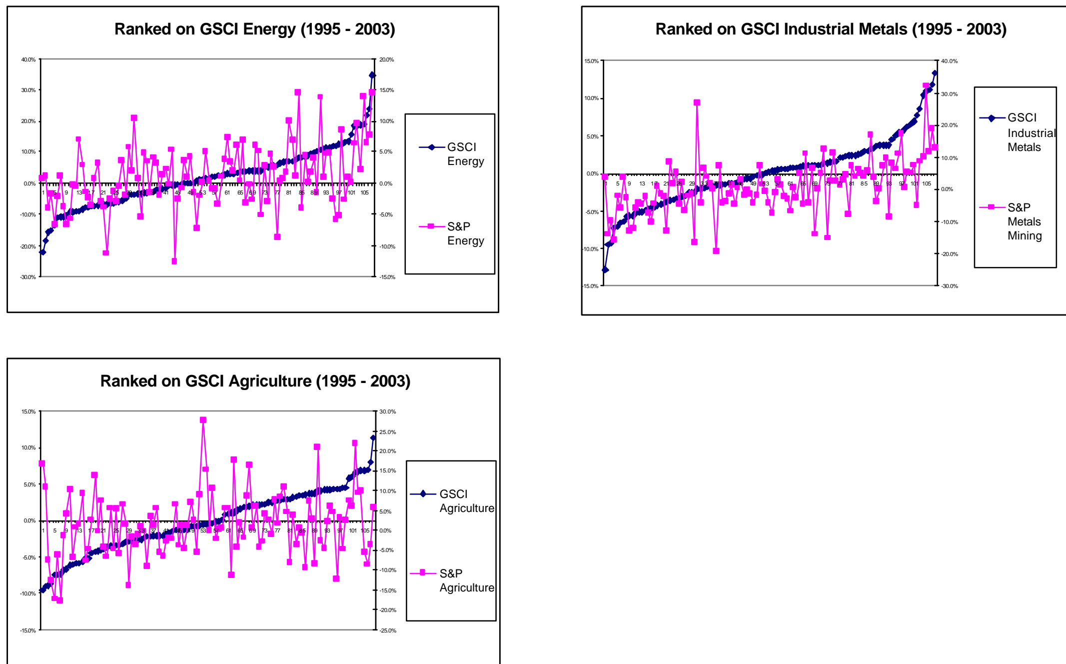
It is well known that many commodity-based firms hedge their exposure to commodity price fluctuations. As a result, investment in commodity-linked equities does not replicate the unique price-return behavior of direct commodity investment. This issue is explored here by studying the relationship between the return properties of commodity-linked equities (S&P Energy, Industrial Metals, and Agriculture) and the corresponding GSCI and DJ-AIG CI. Returns of S&P indices were ranked in ascending order according to the DJ-AIG CI and GSCI, respectively. Exhibit 5 shows plots of the indices in each group.

Exhibit 5-a



It is apparent from the plots that often direct investment in commodities can provide a positive return when commodity-linked stocks lose money. Clearly, direct commodity investment can provide downside portfolio protection in this sense.

Exhibit 5-b



Roll Return

Finally, futures-based commodity investment can benefit from increased roll returns in periods of increased volatility of the underlying commodity and backwardation. For example, monthly roll returns on the GSCI Composite index was ranked against the intra-month volatility of the GSCI Composite spot price index. Exhibit 6-a shows a clear upward trend in average roll return with increasing intra-month spot volatility in the Composite index. Exhibit 6-b contains similar graphs for the six GSCI subindices. The described relationship between spot volatility and roll return is not observed for all commodity groups, but it is quite pronounced in the cases of Energy and Industrial Metals. This explains why the effect is observed in the Composite index as these groups dominate the index.

Mean roll returns and standard deviations for the Composite index and the six subindices in the least volatile and the most volatile 42 months (spot price volatility is meant here) are presented in the first and second columns of Exhibit 7, respectively. For each index, F-tests were run for equal variances of roll returns in the least volatile and the most volatile 42 months. Next, we tested for equality of the means of roll returns in each index/subindex pair, assuming either equal variance or unequal variance, depending on the results from the F-tests. The p-values of the variance and mean tests are presented in the last two columns of Exhibit 7.

As previously suggested by the graphs, mean roll returns for the Energy and Industrial Metals subindices, as well as the GSCI Composite, significantly increase and are positive with increased spot volatility. In contrast, mean roll return for the Livestock subindex decreases and becomes negative. The effect of spot price volatility on the mean roll return of the Agricultural, Non-Energy, and Precious Metals subindices is insignificant. In general, the effect is more pronounced for non-perishable, storable commodities, whose convenience yield rises in periods of increased volatility due to demand and supply shocks.

GSCI Precious Metals	-0.28%	0.38%	-0.08%	0.20%	0.5223	0.0000

Selected Recent Research in Commodity Analysis

Jensen, Mercer, and Johnson [2002] examine the diversification benefits of adding managed and unmanaged commodity futures to a traditional portfolio that consists of U.S. equities, foreign equities, corporate bonds, and Treasury bills from 1973 through 1999. Consistent with previous evidence, they find that commodity futures substantially enhance portfolio performance for investors, and managed futures provide the greatest benefit. They show that the benefits of adding commodity futures (both managed and unmanaged) accrue almost exclusively when the Federal Reserve is following a restrictive monetary policy. The results suggest that metals and agricultural futures contracts offer the most diversification benefits for investors. Overall, the findings indicate that investors should gauge monetary conditions to determine the optimal allocation of commodity futures within a portfolio, and whether a short or a long position should be established in a particular type of contract.

Erb and Harvey (2005) claim that commodity investments are an inconsistent hedge against unexpected inflation. The authors state that usual risk factors are unable to explain the time-series variation in excess returns. They also suggest that historically high returns on commodity futures portfolio are largely driven by the choice of weighting schemes. The authors provide evidence that there are distinct benefits to an asset allocation overlay that tactically allocates using commodity futures exposures. The authors examine three trading strategies that use both momentum and the term structure of futures prices. They find that the tactical strategies provide higher average returns and lower risk than a long-only commodity futures exposure.

In order to study simple properties of commodity futures as an asset class, Gorton and Rouwenhorst (2005) construct an equally-weighted index of commodity futures monthly returns over the period between July of 1959 and December of 2004 The authors suggest that fully-collateralized commodity futures have historically offered the same return and Sharpe ratio as equities; while the risk premium on commodity futures is essentially the same as equities, commodity futures returns are negatively correlated with equity returns and bond returns. The authors state that the negative correlation between commodity futures and the other asset classes is due, in significant part, to different behavior over the business cycle. They also add that commodity futures are positively correlated with inflation, unexpected inflation, and changes in expected inflation.

Recent Performance

Results in Exhibits 8 and 9 show the performance of a number of assets and combinations of assets (traditional assets and commodity indexes) over the past five years (2000-2004). During this period all commodity indexes outperformed US and world equities and bonds (see Exhibit 8). The benefits of diversifying traditional investments by including commodity indexes to a portfolio of stocks and bonds are obvious in Exhibit 9. When added to a portfolio of stocks and bonds, whether domestic or international, all commodity indexes increase returns and lower standard deviations. When added to the portfolio of S&P 500 and Lehman Bond Indexes, JCPI boosts the annualized rate of returns by more than three percentage points, from 3.15% to 6.90%, while the standard deviation declines by 42 basis points. Similar results apply to GSCI and DJ-AIG CI. When included in a portfolio of world traditional securities (MSCI and Lehman Global), the returns are even more stellar. Low or negative correlations between the commodity indexes and all these portfolios suggest such potential benefits.

Conclusions

In recent years, investable commodity indices and commodity linked assets have increased the number of available commodity-based products. This paper has shown that direct commodity investment can provide significant portfolio diversification benefits beyond those achievable from commodity-based stock and bond investment. These benefits stem from the unique exposure of commodities to markets forces such as unexpected inflation as well the potential of a positive roll return in futures-based commodity investment in periods of high spot price volatility. Adding a commodity component to a diversified portfolio of assets has been demonstrated to result in enhanced risk-adjusted performance. We believe that this research would place the use of investable commodity indices as a central part of the institutional investors' asset allocation decision.

The present research can be extended by studying the potential benefits of active trading in various commodity indices. Also, future studies might consider the impact of alternative asset allocation strategies under varying market conditions (e.g., business cycle) and the impact of investment into commodity linked-products or investable commodity indices under these economic conditions.
